NOTES

FIRST RECORD OF Le CONTE’S SPARROW IN OREGON

JEFF GILLIGAN, 26 N.E. 32nd Avenue, Portland, Oregon 97232
OWEN SCHMIDT, 1220 N.E. 17th Avenue #2-D, Portland, Oregon 97232
DAVID IRONS, 4005 S.E. Lambert, Portland, Oregon 97202
RICHARD SMITH, 12415 N.W. Haskell Court #18, Portland, Oregon 97229

Gilligan spotted Oregon’s first Le Conte’s Sparrow (Ammodramus leconteii) while birding with Schmidt, Irons and Smith on 27 Sep 1983, in the tiny oasis town of Fields, Harney Co. We first saw the bird around 0900 in 3 m high willows (Salix sp.) along the creek that flows through town. These trees were filled with migrating passerines including a Blackpoll Warbler (Dendroica striata) and a Clay-colored Sparrow (Spizella pallida), both vagrants in Oregon. The record has been submitted to the Oregon Bird Records Committee.

The Le Conte’s Sparrow soon disappeared into a nearby swale, mostly grassy with small willows and brush that had been killed 2 years earlier by fire. We saw it many times over the next 6 hours, in some cases getting views as long as a minute but usually just catching glimpses. One diagnostic photograph (Figure 1) was obtained when the bird was flushed onto a small snag. The click of the camera shutter frightened the bird back into the grass.

Figure 1. Le Conte’s Sparrow, Fields, Harney Co., Oregon, 27 Sep 1983.

Western Birds 15:185-186, 1984
This description was taken from field notes prepared by Irons and Gilligan immediately after the sighting: Size—small, about the size of a Lincoln's Sparrow (*Melospiza lincolnii*). Head—very pale central crown stripe bordered by a distinct blackish line on each side; broad, bright orange-buff supercilium; black postocular streak; distinct gray ear patch; lower face orange-buff, somewhat paler than supercilium. Bill—short, conical. Eye—large, dark. Nape—grayish, streaked with reddish-brown. Chest—orange-buff. Sides—orangish, well streaked with dark brown. Abdomen—whitish. Back—feathers blackish-brown, broadly edged with buff, forming several broad buffy lines running the length of the back. Wings—brown, feather fringes paler brown. Tail—short; undertail—orangish-buff.

The broad buffy streaks on the blackish-brown back, the distinct gray ear patch, and the orange-buff supercilium eliminate any race of the Grasshopper Sparrow (*Ammodramus savannarum*). The distinct gray ear patch, the streaked nape, the pale crown stripe, and the broadness and buffy color of the back streaks eliminate the inland race of the Sharp-tailed Sparrow (*Ammodramus caudacutus nelsoni*).

Winds were from the southwest on the morning this bird was seen. In fall 1983, as in fall 1982 when we bired the same area on about the same date, “eastern” vagrants were seen at Fields during periods of southwest winds.
