MARTIN RENNER, Memorial University of Newfoundland, Department of Biology, St. Johns, Newfoundland A1B3X9, Canada

On 4 August 2003 we observed and photographed a large dark-mantled albatross (Figure 1) 18 km northwest of Kasatochi Island, in the Aleutian Islands (52° 13' N, 175° 49' W), Alaska. We identified it as a Salvin's Shy Albatross (Thalassarche cauta salvini) (for information on the taxonomy of the Shy Albatross complex, see Cole 2000.) Our observation and photographs provide the first record of this species for Alaska and the 10th record for the North Pacific (Table 1). Of these birds, five were identified as Salvin’s Albatrosses, five as White-capped Albatrosses (T. c. cauta/steadi).

We sighted the bird while traveling on the U.S. Fish and Wildlife Service research vessel Tiłigłax. The weather was clear and calm with a glassy sea. Noticeably larger than Laysan (Phoebastria immutabilis) and Black-footed (P. nigripes) albatrosses in the area, the Shy Albatross was first sighted approximately 300 m from the vessel. Unlike the other albatrosses in the area, this bird had extreme difficulty becoming airborne, and we were able to observe it within 30 m of the vessel for >30 minutes.

This albatross had a light forehead, gray hood, dark mantle, extensive white rump and upper-tail coverts, and an olive-gray bill with an obvious dark nail. The wingspan was considerably larger than that of the other albatrosses nearby. The underwing was mostly white with very narrow black margins and extensive black on the tips of the primaries. We also noted the black preaxillary notch at the base of the underwing, which is characteristic of the Shy Albatross (Marchant and Higgins 1990). The combination of gray hood, bill color, and underwing pattern are consistent with subspecies salvini (Jean-Claude Stahl in litt., Marchant and Higgins 1990, Shirihai and Jarrett 2002). During our observations we noted that the wings were in molt (Figure 2). From the combination of wing molt, dull bill coloration with dark nail, and near-adult plumage we assessed the bird as a subadult (see Shirihai and Jarrett 2002).

Salvin’s Albatross breeds on the Snares and Bounty islands off New Zealand (ca. 76,000 pairs) and on Penguin Island in the Crozet Island group (<5 pairs; Enticott and Tipling 1997). Subadult birds forage widely in the South Pacific, ranging north to about 5° S latitude along the west coast of South America (Marchant and Higgins 1990). Seabird authority Sandy Bartle (in litt.) opined that our bird probably drifted north from those waters via the California Current. Salvin’s Albatross is classified as vulnerable because of probable population decline and because breeding is restricted to one tiny island group (Statessfield and Capper 2000, IUCN Red List for birds).

Many observers were present when this bird was sighted, and identification was aided by Daniel C. Barton, Jeffrey C. Williams, Kirsten E. Lindquist, Donald E. Dragoo, and Kevin D. Bell, besides us. We thank Kevin D. Bell and the crew of the M/V Tiłigłax for a memorable trip. Photos were provided by Kenneth S. Gates. Thanks to Luke W. Cole, Stephen F. Bailey, Thomas J. Evans, and Steven G. Mlodinow for their help and review. Confirmation of identification from the photos and video capture was made by Sandy Bartle and Jean-Claude Stahl, Museum of New Zealand, Te Papa Tongarewa. Thanks to Daniel D. Gibson and the Alaska Checklist Committee for assistance with this manuscript.
